

TRAIN SMARTER WITH AI-POWERED **TRIATHLON TRAINING**

LESS TRAINING. BETTER RESULTS. FEWER INJURIES.

GET FASTER, FASTER

GET DATA-DRIVEN TRAINING.
TRIDOT'S AI HAS PRESCRIBED 110M+ TRAINING SESSIONS.

TriDot AI is truly data-driven.

LEARN MORE ABOUT OPTIMIZED TRAINING

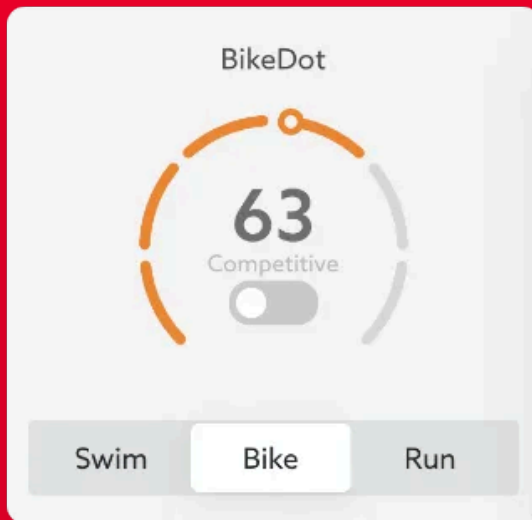

ELEMENTS OF AI-POWERED TRAINING

TRIDOT SCORES NORMALIZE PERFORMANCE ABILITY

TriDot Scores are performance ability measures for each discipline for triathletes. They allow you to see your relative strength across disciplines, including on an “equalized” basis that normalizes for age and gender. Your SwimDot, BikeDot, and RunDot Scores reflect your normalized functional threshold power or pace (FTP) on a 1 to 100 scale with 1 being the slowest and 100 being at or near world-record pace.

TRIDOT FACTORS YOUR ENVIRONMENT

The environment in which you train and compete dramatically impacts your ability to perform. Environment Normalization makes data-driven adjustments to your training and race pace prescriptions to account for these environmental elements:

✓ Training/Racing with EnviroNorm®

TriDot uses EnviroNorm to adjust your prescribed paces to account for your training environment (indoor/outdoor, weather, such as temperature and humidity, and terrain, including elevation). By doing this, TriDot's intensity recommendations are always spot on. You'll train with the perfect level of training stress for your training conditions. Likewise, when racing, you'll be prescribed paces that are the optimal paces for you given the set of weather and terrain conditions you will face on race day.

✗ Training without EnviroNorm®

A training session performed on a cool morning at 55° F and 40% humidity would be a completely different training experience if it was performed in the afternoon at 90° F and 80% humidity.

The morning session might be perfect and drive the desired training adaptations, but if your coach or plan does not account for your training environment (indoor/outdoors, weather and elevation) the same session done that afternoon might not even be achievable. And it could cause significantly more training stress and injury risk than desired.

TRIDOT MORE ACCURATELY MEASURES TRAINING STRESS

TriDot's proprietary training stress metric, Normalized Training Stress™ (NTS™), is triathlon's most comprehensive method of quantifying physiological stress from a training session. Unlike a Training Stress Score (TSS), which has been used for years but now is outdated, NTS considers your training session's discipline type, environment, intensity distribution, intensity levels, intensity durations, and your Training Stress Profile™ (your ability to absorb training stress).

**TRIDOT FACTORS
YOUR GENETICS**

LEARN MORE ABOUT PHYSIOGENOMIX™

An optional feature, Physiogenomix™, leverages our AI-powered engine to offer unparalleled training optimization based on your genetic profile. It analyzes your genome to measure your Training Intensity Response, Aerobic Potential, Recovery Rate, and Injury Predisposition and optimize your training.

We value your privacy

Injury Predisposition

Injury Predisposition is a measure of how genetically prone you are to incurring soft-tissue (tendon and ligament) injuries from training.

Training Impact

Your Injury Predisposition primarily influences training intensity and volume, specifically related to high-intensity sessions and rates of increasing volume and long session durations. It can also influence the type warm-up drills and strength training routines that contain high-impact, ballistic movements.

Aerobic Potential

Aerobic Potential is a measure of your potential for developing a high aerobic capacity or high oxygen utilization (VO₂max). This is not a measure of your current aerobic capacity. Rather, it is a measure of your aerobic trainability--your potential for improvement with proper training.

Training Impact

Aerobic Potential influences how quickly and to what degree you are able to increase your aerobic fitness. This can impact improvement-rate expectations used when optimizing training focus and periodization of training blocks in both

Recovery Rate

Recovery Rate is a measure of your genetic ability to recover from exercise-induced oxidative stress and inflammation. This includes the level of stress and inflammation produced and the rate at which it is cleared.

Training Impact

Your Recovery Rate primarily influences training intensity and frequency, specifically with regard to higher intensity sessions. It can be used proactively when prescribing training to help ensure planned sessions don't include more training stress than you have time to recover from prior to your next

Training Intensity Response

Training Intensity Response is a relative measure of how you respond to high-intensity versus low-intensity training. Based on your genetic variations, you are predisposed to have a greater response to either high or low-intensity training.

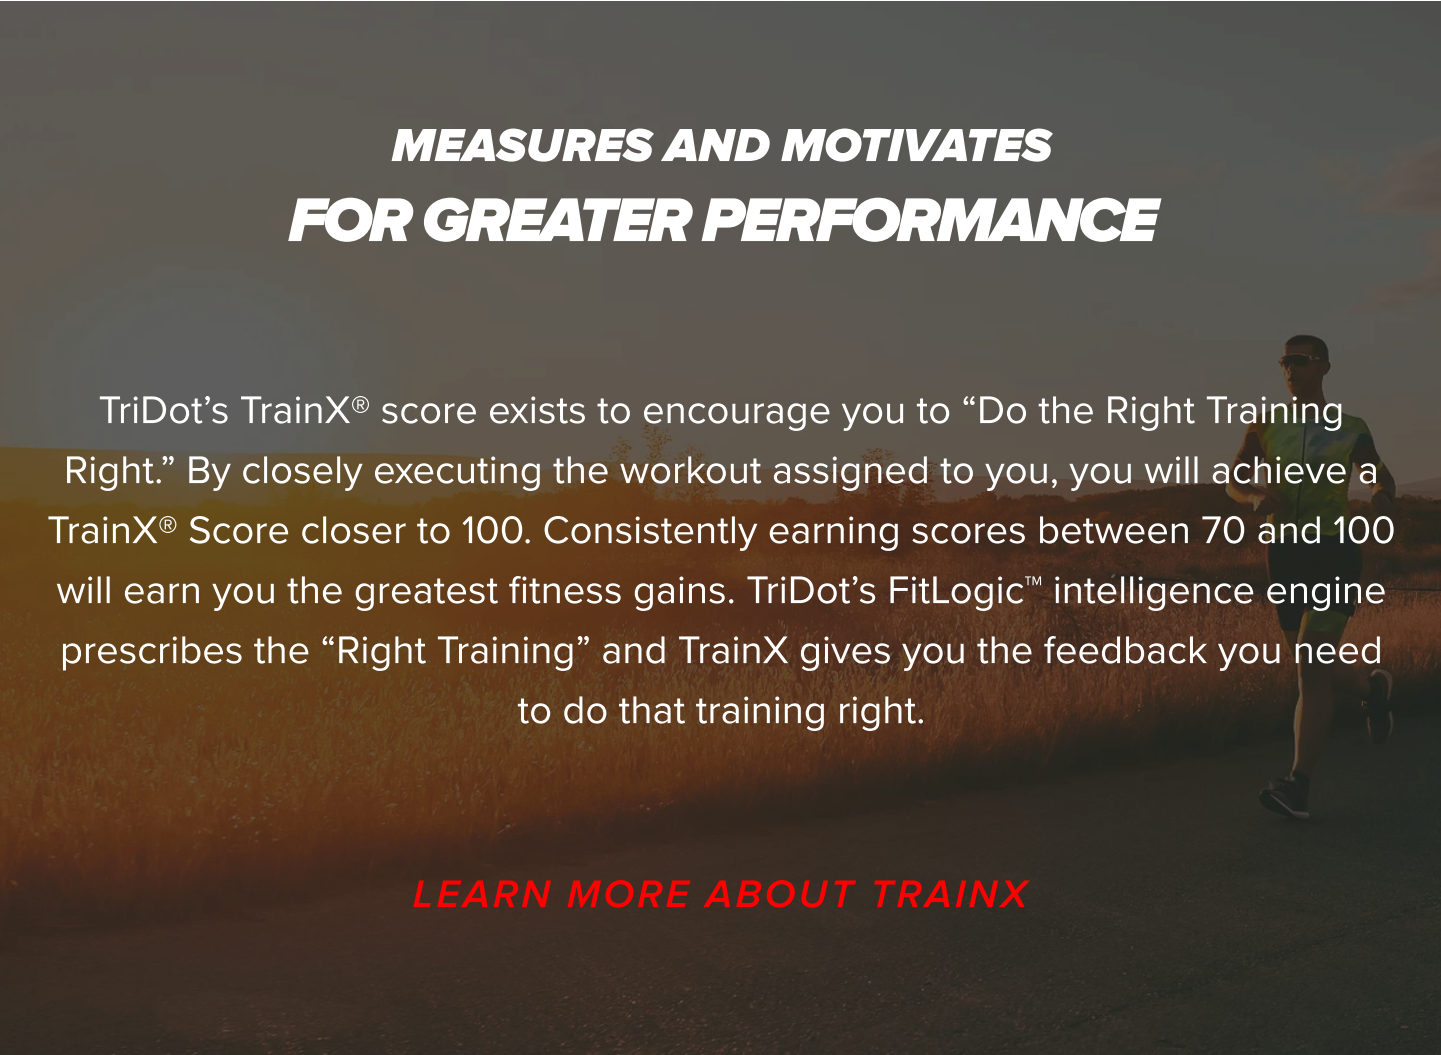

Training Impact

Training Intensity Response influences your training emphasis and improvement expectations, specifically related to differences between training above your functional (aerobic) threshold versus at or below it. Proper emphasis and expectations help to ensure that training time and intensities

MEASURES AND MOTIVATES FOR GREATER PERFORMANCE

TriDot's TrainX® score exists to encourage you to “Do the Right Training Right.” By closely executing the workout assigned to you, you will achieve a TrainX® Score closer to 100. Consistently earning scores between 70 and 100 will earn you the greatest fitness gains. TriDot's FitLogic™ intelligence engine prescribes the “Right Training” and TrainX gives you the feedback you need to do that training right.
